Introduction

In the Great Lakes, as well as in the coastal oceans the gradients of many biogeochemically important materials (BIMs) are considerably higher in the offshore direction than in the longshore direction (Brink et al., 1992). In the presence of these large gradients, cross-isobath circulation is a primary mechanism for the exchange of material between nearshore and offshore waters. In the coastal regions of the Great Lakes it has been observed that the mean alongshore transport is much larger than the cross-shore transport. However, both the alongshore and cross-shore current components exhibit strong episodic behaviour due to wind forcing. In order to understand the cross-shore transport of BIMs and quantify the physical processes that are responsible for the nearshore-offshore mass exchange, a multidisciplinary research program, EEGLE (Episodic Events Great Lakes Experiment) was recently initiated by NOAA (National Oceanic and Atmospheric Administration) and NSF (National Science Foundation) in Lake Michigan (Eadie et al., 1996).

Experimental Data

The observation strategy for obtaining the cross-shore and alongshore currents, physical environment, and temperature consisted of three components: (a) moored instruments (b) Lagrangian measurements and (c) ship-board surveys. In the moored instrumentation time series of currents, winds, and temperature data were obtained for the field years of 1997 to 2000. A maximum of 17 moorings of ADCPs and VACMs were deployed from the 20 m to 60 m depth contours by GLERL (Great Lakes Environmental Research Laboratory). As a part of the program the National Water Research Institute (NWRI) deployed additional instrumentation consisting of seven SACMs, and two ADCPs in the shallow waters at a depth of 12 m along with two coastal meteorological stations. The complete details of the observational strategy is reported in EEGLE website (<http://www.glerl.noaa.gov/eegle>). In this first data report we summarize the data from current meter moorings deployed in 1997-98.

Data Presentation

Some of the methods used to display the data here are consistent with the previous CCIW Limnological Summaries (i.e., Bull, Farooqui *et al*, 1976, Jordan and Bull, 1977). The hourly averaged data are time-series collection of meteorological, current and temperature measurements.

To analyse the wind and current data extensive use were made of rose histograms.

Tabular Statistical Summaries: Hourly values of wind and current data were divided into three speed classes (0-3, 3-7, and greater than 7 m/sec for the wind and cm/sec for the current and into eight compass sectors. The mean duration is defined as the average time a current direction remained in the sector. The mean excursion is the product of the mean duration and the mean current.

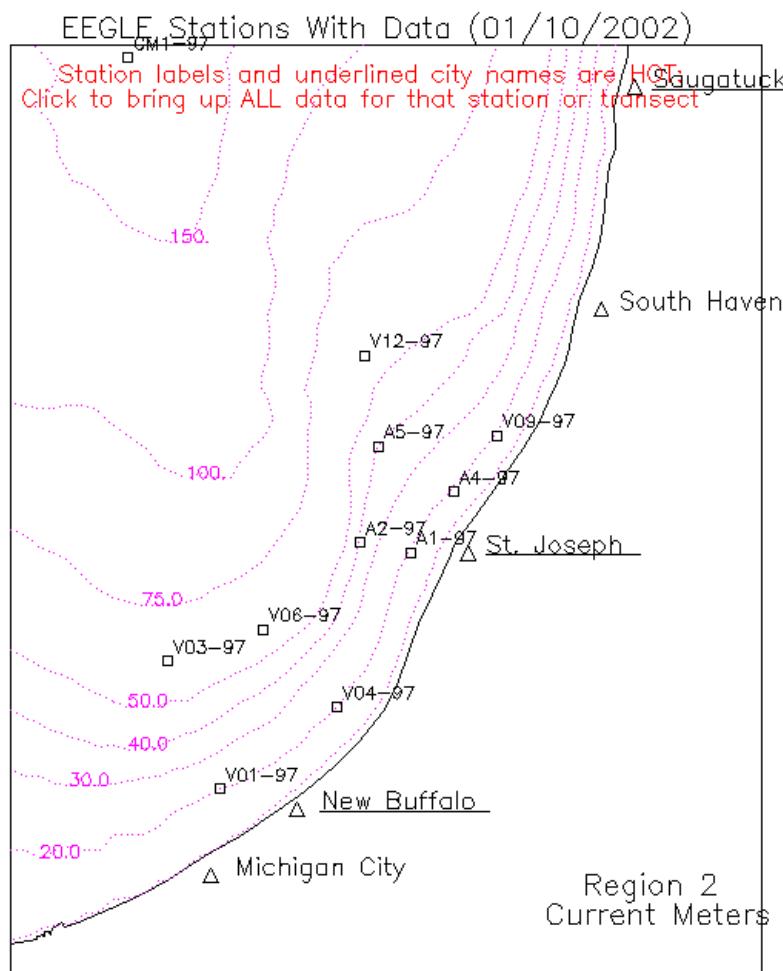

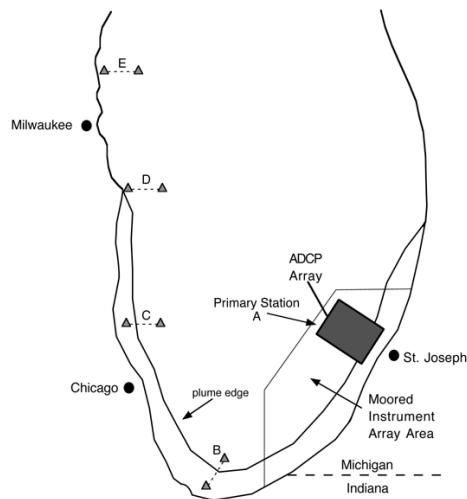

The mean scalar speed, mean square speed, mean square (E-W, N-S, U, V), mean velocity and direction and variance are summarised below the table. The mean temperature, as measured by the current meter, is also given.

Wind and current rose histogram plots: Hourly data of wind and current were tabulated and classified by speed and direction. Speed classes were defined as 0 to 3, 3 to 7, and greater than 7 m/sec or cm/sec for wind and current respectively. Direction classes were defined into 8 equal sectors of 45 degrees. Wind and current directions are “towards”.
